EXAMINING THE DIFFERENTIAL LONGITUDINAL PERFORMANCE OF DIRECTIVE VERSUS EMPOWERING LEADERSHIP IN TEAMS

This study integrates theories from the leadership and team development literatures to resolve ambiguity regarding the relative benefits of empowering and directive leadership in teams by focusing on their influence on team development processes over time. Empirical results based on longitudinal performance data from 60 teams suggest that teams led by a directive leader initially outperform those led by an empowering leader. However, despite lower early performance, teams led by an empowering leader experience higher performance improvement over time because of higher levels of team learning, coordination, empowerment, and mental model development. Implications for current and future team leadership research are discussed.

In response to the increasing organizational reliance on teams to perform complex tasks, leadership research has gradually shifted its focus toward examining the important role of leaders in improving team performance and adaptation (e.g., Burke, Stagl, Klein, Goodwin, Salas, & Halpin, 2006; Klein, Ziegert, Knight, & Xiao, 2006). Team leadership research has concentrated on the leader behaviors that promote, develop, and maintain team performance, and two distinct approaches—empowering and directive leadership—have assumed special importance (Srivastava, Bartol, & Locke, 2006; Yun, Faraj, & Sims, 2005).

Empowering leadership involves sharing power with subordinates and raising their level of autonomy and responsibility, and it manifests through specific behaviors such as encouraging subordinates to express opinions and ideas, promoting collaborative decision making, and supporting information sharing and teamwork (Arnold, Arad, Rhoades, & Drasgow, 2000; Chen, Sharma, Edinger, Shapiro, & Farh, 2011; Pearce, Sims, Cox, Ball, Schnell, & Smith, 2003; Yun et al., 2005). Empowering leadership tends to create psychological ownership of a task, heightened efficacy and commitment, and higher levels of coordination and collective information processing (e.g., Cohen, Chang, & Ledford, 1997; Zaccaro, Rittman, & Marks, 2001).

Directive leadership, on the other hand, is associated with a leader’s positional power and is characterized by behaviors aimed at actively structuring subordinates’ work through providing clear directions and expectations regarding compliance with instructions (e.g., House, 1971; Pearce et al., 2003; Somech, 2006; Yukl & Falbe, 1991). Directive leaders help followers resolve task and role ambiguity and provide external monitoring and feedback on their performance, reducing process loss and allowing team to execute decisions more quickly (House, 1996; Kahai, Sosik, & Avolio, 2004; Sagie, 1997).

Although researchers and the practitioner-oriented literature have advocated empowering over directive leadership, the empirical evidence has not fully supported this view, and it is not clear that empowering leadership is actually better for enhancing team performance (e.g., Ensley, Hmieleski, & Pearce, 2006; Kahai et al., 2004; Ma-
The extant leadership research has thus far neglected two important issues that may help shed light on this question. First, the literature generally exhibits a cross-sectional perspective on leader effectiveness, focusing on whether directive or empowering leaders are beneficial overall but overlooking the question of when empowering leadership might be most or least effective. Second, although research acknowledges the importance of team member skills and attitudes in the effectiveness of various leadership approaches (e.g., Thompson & Vecchio, 2009), it has yet to examine the direct influence leaders have on the development process of teams or why empowering leadership may provide its promised benefits to teams over time (e.g., Klein et al., 2006; Yukl & Lepsinger, 2004). This is especially true for newly formed teams, where time plays a critical role in understanding the interplay between team development and leadership (e.g., Kozlowski, Gully, Nason, & Smith, 1999; Kozlowski, Gully, Salas, & Cannon-Bowers, 1996; Yukl & Lepsinger, 2004).

In response, we address these key conceptual and empirical problems by (a) examining the relative influence of empowering and directive leadership on the performance of teams over multiple phases of team interaction and development and (b) identifying critical behavioral, motivational, and cognitive mechanisms that explain the differences between empowering and directive leadership in teams over time. Because of the influence of leaders on internal team processes and emergent states (e.g., Mathieu, Maynard, Rapp, & Gilson, 2008), the choice of leadership approach in any focal phase of team development will have implications for both current and future team interactions and performance.

Therefore, drawing on Kozlowski et al.’s (1999) model of team compilation and adaptation, we offer a more nuanced description of the costs and benefits of empowering leadership in teams by first arguing that the initial guidance and role definitions provided by directive leaders will help their teams to outperform empowered teams in the short term. However, we argue that, owing to the shared learning and decision-making climate that empowering leaders create in the initial phases of team development, and the resultant emergence of collective states and processes in teams, empowered team members will be able to attain higher levels of performance through the later phase of team development, while teams with directive leaders will be less able to improve. We then identify behavioral, motivational, and cognitive processes and states in teams that explain the improved performance of empowering versus directive leadership over time: team learning, behavioral coordination, psychological empowerment, and team mental models.

By doing so, we hope to extend the empowering leadership literature in two important ways. First, by demonstrating that teams led by an empowering leader achieve greater long-term performance improvement, but at the cost of initial performance delays, we help resolve ambiguity about the benefits of each leadership type through explicating the trade-offs and boundaries of empowering leadership in teams. Second, by identifying key emergent states and processes in teams that result from empowering leadership and convey its influence into future performance, we shed light on the underlying question of why the initial performance costs of empowering leadership may be worthwhile in the long run.

Apart from contributing to the empowering leadership literature, this study also extends other extant theories of leadership. In particular, the prescription of empowering or directive leadership based on follower readiness has been a central tenet of situational leadership theories (e.g., Hersey & Blanchard, 1969, 1982; Vroom & Jago, 1988). For example, Hersey and Blanchard (1982) highlighted follower attributes such as emotional maturity and readiness to be empowered that indicate the extent to which followers are able to share ideas and find motivation in greater responsibility (e.g., Chen, Kirkman, Kanfer, Allen, & Rosen, 2007; Spreitzer, 1995). However, situational leadership theories have found only limited empirical support (see Thompson & Vecchio, 2009), in part due to ambiguity as to the nature of follower readiness—a particularly complex consideration for leaders of collections of individuals in a team context. As we will describe, this study also extends aspects of situational leadership theory by providing a more comprehensive way of conceptualizing follower readiness that is specific to the team level and by suggesting limits to the notion that initially directed teams will eventually be ready to receive and respond to empowering leadership.

THEORETICAL BACKGROUND

Given its focus on sharing power with employees and emphasizing collaboration (Arnold et al., 2000; Manz & Sims, 1987), empowering leadership has
been touted as particularly suited to meet the needs of leading teams of people (e.g., Kirkman & Rosen, 1999; Pearce et al., 2003). However, researchers have not always succeeded in finding support for the proposed benefits of empowering leadership on team intermediate and final outcomes (e.g., Mathieu et al., 2006), with a number of studies finding evidence that not empowering leadership, but its obverse—directive leadership—leads to higher performance in teams (e.g., Ensley et al., 2006; Kahai et al., 2004; Yun et al., 2005). Therefore, despite the association of both leadership styles with positive team outcomes (e.g., Sagie, Zaidman, Amichai-Hamburger, Te’eni, & Schwartz, 2002), the relative benefits of empowering and directive leadership in influencing team performance remain unclear (Somech, 2006; Sosik, Avolio, & Kahai, 1997).

Each style tends to enhance follower performance because both directive and empowering leaders are actively attempting to improve team effectiveness through thoughtful, planned behaviors. Empowering leadership tends to benefit interdependent teams by establishing participative and collaborative norms among members, encouraging them to contribute ideas, decide on optimal courses of action, and take responsibility for team performance. These types of behaviors tend to lead to positive individual and work group outcomes across contexts (e.g., Pearce et al., 2003; Yukl, 1998). For example, Zhang and Bartol (2010) recently provided evidence that empowering leadership enhances employee creativity, through its effects on employee psychological empowerment, intrinsic motivation, and creative process engagement. Similarly, Ahearne, Mathieu, and Rapp (2005) found a positive relationship between leader empowering behaviors and followers’ job performance attributable to increased levels of self-efficacy and adaptability. At the team level, the goal of empowering leadership is to develop a team’s capacity to perform autonomously (Manz & Sims, 1987). Though similar to participatory leadership, which “involves the use of decision procedures intended to allow other people some influence over the leader’s decisions” (Yukl, 1998: 83), empowering leadership requires leaders to invest more trust in their followers by allowing high levels of discretion and decision-making authority to pass into the followers’ hands.

However, a directive approach, which is similar to the autocratic leadership style in Vroom and Jago’s (1988) decision model and the “tough leadership style” of McIntyre and Salas (1995), focuses on behaviors related to giving detailed directions, expecting subordinates to follow those instructions, and making decisions with limited subordinate input. Research suggests that superiors’ directiveness can make task accomplishment easier for followers by providing them with specific, role-relevant directions and helping them focus their efforts toward their individual tasks (Fiedler, 1968; Kahai et al., 2004). Additionally, directive leadership helps each individual to be better aware of his/her own role and the availability of role resources (Yukl, 1998), reducing ambiguity about what each person does (Kahai et al., 2004; Pearce et al., 2003) and establishing clear rules for behavior (e.g., Katzenbach & Smith, 1993). For example, research has shown that directive leadership can lead to improved patient care through the assignment of specific actions for handling an emergency situation (Yun et al., 2005). This is in contrast to empowering leadership, in which the higher degree of freedom and discretion granted to team members allows more potential paths toward attaining a goal, potentially decreasing task and role clarity (Evans, 1970; House, 1971).

Situational leadership theories—conceived as a means of providing practical advice to managers as to when to best apply each different leadership style—are based on the principle that the relative benefits of each leadership type will depend on the competence, maturity, or readiness of followers (e.g., Goodson, McGee, & Cashman, 1989; Hersey & Blanchard, 1969, 1982; Thompson & Vecchio, 2009). Subordinates with low levels of readiness, such as new employees with limited skills but sufficient motivation, are expected to benefit from a telling, or directive, leadership approach, which entails giving specific instructions to subordinates, as well as monitoring their progress and providing feedback (e.g., Muczyk & Reimann, 1987; Sims, Faraj, & Yun, 2009; Yun et al., 2005). On the other hand, in the case of followers with higher levels of readiness and with sufficient competence, efficacy, and commitment, situational leadership theories suggest that participating and delegating styles of leadership should be most effective (e.g., Blanchard, 2007). In terms of situational leadership theory, empowering leadership falls most closely in line with delegation, though as a practical matter it is difficult to distinguish between delegation and high levels of participatory leadership (see Thompson & Vecchio, 2009).
Follower readiness was initially defined as “the extent to which a follower has the ability and willingness to accomplish a specific task” (Hersey & Blanchard, 1988: 174). Addressing criticisms by scholars (see Northouse, 2007), Blanchard (2007) revised the definition with a clearer conceptual typology that combines the follower attributes of competence and commitment to create discrete levels for “developing” versus “developed” followers. However, though member competence may play an important role in team effectiveness, the readiness of teams to respond effectively to empowering leadership is more complex, as it is based on the degree to which a team has developed the cognitive, motivational, and behavioral capabilities which are critical for long-term team effectiveness (e.g., Burke, Stagl, Salas, Pierce, & Kendall, 2006). Thus far, situational leadership theory has failed to take into account the development of these attributes when conceptualizing team readiness.

**Team Development**

Teams do not simply manifest collective competence and commitment when needed. Rather, their readiness is temporally bound by the focal stage of their members’ collective development (Kozlowski et al., 1996; Zaccaro et al., 2001), and each leadership approach directly influences how effectively teams mature in critical phases of their evolution. According to Kozlowski et al.’s (1999) model of team development, the process occurs over four distinct phases during the initial periods of team composition and adaptation (see Figure 1, “Effects of Leadership in Team Development Phases”). During the first phase, *team formation*, a team’s members come together to begin the socialization process during which they develop an understanding of the team’s collective purpose and start to think of themselves as a team. During the second phase, *task compilation*, individual team members tend to focus their attention on individual task mastery and proficiency and remain “primarily self-focused on their individual task performance” (Kozlowski et al., 1999: 262). During these initial phases, the role of the leader is primarily felt through socializing the followers into the organization or group and ensuring that they develop the necessary skills to perform their tasks.

In the third phase, *role compilation*, team members begin to learn to coordinate their performance with other team members through a process of sharing and receiving role information and clarifying role expectations (Graen & Scandura, 1987; Katz & Kahn, 1978). In this phase, the influence of active leadership begins to be felt most keenly, as leadership interventions during role compilation are likely to influence the nature and the quality of these interactions (Kozlowski et al., 1999). Specifically, we argue that directive leadership and empowering leadership will differentially affect team development and performance because of their

**FIGURE 1**

Effects of Leadership in Team Development Phases

- Directed teams: Reduced capacity for learning and integration of expertise, reliance on individual knowledge and leader coordination.
- Empowered teams: Focus is on performance improvement using behavioral routines and shared cognitions developed in phase 3.

* Adapted from Kozlowski et al. (1999).
differing influence on team role compilation processes.

During role compilation, team members should navigate their role interactions, learning about their own and their teammates’ responsibilities and capabilities through a series of role identification and clarification behaviors. This navigation allows them to begin using their knowledge of one another to integrate their efforts, resulting in the development of routinized processes and the emergence of shared cognitive structures (e.g., Pearsall, Ellis, & Bell, 2010). However, team members with directive leaders largely bypass these processes, as the leader gives specific role guidance and provides detailed goals and instructions for each team member, thus actively managing their interactions (e.g., Korsgaard, Schweiger, & Sapienza, 1995; Sagie, 1996).

For example, task execution directions given by a leader are likely to trigger individual member’s efforts to perform their role-specific task requirements and to obviate the need to learn about their teammates’ roles to ensure their efforts are integrated. Directive leaders, therefore, act as explicit coordination mechanisms for their teams, removing the need for the time-consuming development of learned routines and shared cognitions (Espinosa, Lerch, & Kraut, 2004). Thus, directive leaders are likely to quickly benefit initial team performance by focusing team members’ attention on executing their specific tasks.

Empowering leaders, on the other hand, will tend to first work to establish norms for collaborative decision making during the role compilation phase. With behaviors emphasizing the open exchange of ideas and suggestions within a team, empowering leaders will attempt to create an atmosphere of increased interaction among team members, which aids individuals’ understanding of “who they interact with to perform the task” (Kozlowski et al., 1999: 266) and the development of shared perceptions and understanding. Therefore, during the role compilation phase, teams led by an empowering leader are likely to focus on developing knowledge of each other and experiencing positive interpersonal interactions, rather than on performing (Kozlowski et al., 1999).

Directive leadership during the role compilation phase should therefore be most effective for performance in teams. Teams with a directive leader will be able to sustain their focus on task performance, relying on the explicit guidance provided by their leader. In contrast, because empowering leaders attend to team members’ involvement in decision making and encourage experimentation, learning, and collaborative contributions (Arnold et al., 2000; Leana, 1987; Pearce et al., 2003; Srivastava et al., 2006), teams with an empowering leader will initially take longer to effectively perform their tasks. This should enable directly led teams to outperform empowered teams during the role compilation phase of team development. Therefore, we hypothesize:

**Hypothesis 1. Teams led by a directive leader exhibit higher initial performance than teams led by an empowering leader.**

Although directive leaders offer teams an initial performance advantage in the role compilation phase, team performance and adaptability in the fourth phase, *team compilation*, depend heavily on the role interactions and implicit coordination mechanisms that are expected to emerge during the previous phase (Kozlowski et al., 1999). Through emphasizing team members’ involvement in decision making, open communication, and sharing of ideas and opinions, empowering leaders further enable learning and coordination by creating a climate in which high levels of knowledge exchange are encouraged (Burke et al., 2006; Manz & Sims, 1987; Srivastava et al., 2006).

Through these processes, a team develops the collective competence, confidence, and commitment that make empowering leadership most effective in the team compilation phase. In directed teams, however, the initial performance gains during role compilation come at the price of a reduced capacity for learning and integration of expertise during team compilation. Because directed team members have had less need to engage in role identification behaviors and develop shared cognitions about their roles and team task, they are left less capable of adapting to their task environment and dealing with uncertainty and complexity. Their team is, therefore, less able to take advantage of the diverse skills and knowledge of its members and is dependent upon, and limited by, the guidance of the directive leader, who must continue to serve as the sole explicit coordination mechanism for the team.

Therefore, although directive leaders may be more effective in maximizing the performance of teams in the short term, their actions prevent the teams from developing the very processes and emergent states that would allow them to be ready for the leader to follow the prescription of situational leadership theory to switch to empowering
leadership as the teams mature. Empowering leaders, on the other hand, despite initial performance delays due to their modeling and emphasizing frequent interpersonal knowledge and idea exchanges (instead of focusing specifically on task performance), should better enable the development of information-sharing norms and cognitive structures to prepare teams to make effective decisions and skillfully perform their tasks over the long run. We hypothesize that:

**Hypothesis 2.** Teams led by an empowering leader exhibit greater performance improvement in the later, team compilation, phase of development than teams led by a directive leader.

Although research on follower readiness in teams has focused on the individual attributes and perceptions of team members (Goodson et al., 1989; Mathieu, Ahearne, & Taylor, 2007; Vecchio, 1987), competence and commitment at the team level are far more complex and hinge on the emergence of shared teams states and processes that enable effective task interaction and performance. For teams with high levels of interdependence and differentiated expertise, long-term effective performance and adaptation result from the development of cognitive, motivational, and behavioral states and processes that convey the effects of leadership onto distal team performance (e.g., Ilgen, Hollenbeck, Johnson, & Jundt, 2005). Drawing on Kozlowski et al.’s (1999) model of team development and Burke et al.’s (2006) model of team adaptation, we focus on four critical emergent states and processes that serve both as markers of collective team readiness and mediators of the relative influence of empowering leadership on performance improvement: team learning, behavioral coordination, psychological empowerment, and team mental models. Together, we argue, these four states and processes will explain the difference in the performance of empowering leadership and directive leadership over the later, team compilation, phase of team development.

Behavioral Processes: Team Learning and Coordination

During team compilation, team members turn their focus to successful task completion and behavioral adaptation. We suggest that the performance improvement in teams with empowering leaders during team compilation will be due, in part, to the increased ability of such teams to learn and to coordinate their knowledge and actions.

Team learning is “the process by which relatively permanent changes occur in the behavioral potential of the group as a result of group interaction activities through which members acquire, share, and combine knowledge” (Burke et al., 2006: 1190; Edmondson, 1999) and is instrumental in allowing teams to understand and adapt to their environment. This behavioral process is of particular importance for teams with distributed expertise, whose members have to synchronize and leverage diverse skills and abilities to perform complex tasks. As noted previously, teams with empowering leaders will engage in greater levels of role identification and discussion during the role compilation phase, leading to a shared understanding of teammates’ roles and capabilities. This knowledge acts as a cognitive foundation for information acquisition and exchange during team compilation (Burke et al., 2006), allowing for improved team performance over time.

Similarly, behavioral coordination, which involves “information exchange and mutual adjustment of action in order to align the pace and sequencing of team member contributions” (Marks, Mathieu, & Zaccaro, 2001: 368) is seen as a critical behavior for interdependent teams as it reflects the smooth integration of skills and knowledge between members. The shared understanding of each other’s roles, duties, and capabilities in teams with empowering leaders will allow team members to exchange information and synchronize actions, improving task performance over time.

In contrast, teams with a directive leader, who limits team members’ input in decision making and does not consult with subordinates, should be less likely to share the information and knowledge held separately by different team members. Because the directive leader acts as the source for guidance and
direction, individual members will tend to focus on their own responsibilities rather than on communicating and sharing with the team (Pearce et al., 2003; Sagie, 1996). Further, a directive leadership style may hamper the development of psychological safety in the team, as the leader does not solicit and encourage input (Edmondson, 1999). Team members in directed teams may, therefore, be much less likely to engage in the experimentation, reflective communication, and knowledge codification that typify effective team learning and coordination (Gibson & Vermeulen, 2003). Without these related behavioral processes, teams with directive leaders are less likely to capitalize on their strong start and, ultimately, are less able to improve their performance over time.

Therefore, we hypothesize:

**Hypothesis 3.** The greater performance improvement associated with empowering compared to directive leadership during team compilation is partially explained by team learning.

**Hypothesis 4.** The greater performance improvement associated with empowering compared to directive leadership during team compilation is partially explained by team behavioral coordination.

**Motivational State: Psychological Empowerment**

The most direct influence of empowering leadership on team interaction manifests through a feeling of psychological empowerment in a team (Chen et al., 2011; Mathieu et al., 2006). Because empowered employees feel more competent and able to influence their team’s outcomes, empowerment has consistently been shown to lead to higher levels of employee commitment, innovation, citizenship behaviors, and performance (e.g., Seibert, Wang, & Courtright, 2011; Spreitzer, 2008; Thomas & Velthouse, 1990; Yukl, 2010). These feelings of competence and commitment that emerge from empowering leadership likewise make a team particularly ready for empowering leadership in the future. Empowered team members will tend to be motivated by collective ownership of their choices and work, to support and back each other up, and to work toward adaptation and performance improvement during team compilation (e.g., Chen et al., 2007; Kirkman & Rosen, 1999; Kirkman, Rosen, Tesluk, & Gibson, 2004).

Therefore we hypothesize that:

**Hypothesis 5.** The greater performance improvement associated with empowering compared to directive leadership during team compilation is partially explained by team empowerment.

**Cognitive State: Team Mental Models**

Mental models are collective knowledge structures that allow team members to understand and form expectations concerning other team members’ responsibilities, needs, and behaviors (Mohamed, Klimoski, & Rentsch, 2000). Because they enable team members to interpret information in a similar manner (Hinsz, Tindale, & Vollrath, 1997), team mental models have been positively related to team processes such as communication (Marks, Zaccaro, & Mathieu, 2000), decision making, and situational awareness (Mathieu, Heffner, Goodwin, Cannon-Bowers, & Salas, 2005), as well as performance in many situations (e.g., Edwards, Day, Arthur, & Bell, 2006; Marks et al., 2000).

During the role compilation phase, empowered team members will tend to engage in dyadic exchanges with their teammates regarding the nature and scope of each team member’s roles and capabilities, helping them to understand the patterns of behavior and interaction that are emerging in their team. As team members explore the boundaries and extent of each others’ expertise and duties, they begin to develop a clear picture of how their unique knowledge, skills, and abilities fit together and how best they can integrate them (Katz & Kahn, 1978; Kozlowski et al., 1999).

Then, during team compilation, as teams shift their focus more toward task execution, their mental models allow them to revise and refine the flow of work and to continuously improve performance (Pearsall et al., 2010). Teams with directive leadership, however, have relied on the explicit direction from the leader rather than engaging in time-consuming role identification interactions and will have less developed mental models to help integrate their efforts.

Therefore, we hypothesize that:

**Hypothesis 6.** The greater performance improvement associated with empowering compared to directive leadership during team compilation is partially explained by team mental model development.
METHODS

Research Participants

Participants in this study included 300 senior undergraduate students enrolled in an upper-level management course at a major mid-Atlantic university in the United States. Participants were arrayed in 60 five-person teams that engaged in a three-hour computer simulation task. In exchange for their participation, participants were given extra course credit and were eligible for cash prizes based on their performance ($250 per team).

Task

Participants were randomly assigned to teams and, with the exception of each team leader, randomly assigned to team roles. They then worked collectively to complete tasks within a networked computer simulation—the Leadership Development Simulator (LDS)—originally developed for the Squadron Officer School at Maxwell Air Force Base and used to train and evaluate midcareer officers (see Davison, Hollenbeck, Barnes, Sleesman, & Ilgen, 2012). The LDS is a complex task in which teams of four staff members and one leader must manage a large number of assets (48 in each round) to discover and interact with targets on a shared task screen over ten rounds of decision making. To be successful, team members must collaborate, combining their efforts to achieve certain objectives (such as attacking a large target or verifying intelligence), which, in turn, produce a higher performance score.

Team members and their leader were seated around a table, each in front of a separate computer station, and were able to freely talk with each other throughout the simulation. Each team member had a defined role with assigned responsibilities, arranged in a functional hierarchical structure containing staff members (the four players) and a formal leader. Each staff member was in charge of either “operation” assets or “intelligence” assets that could be used to gather and employ information about enemy targets (described below).

Teams were in charge of assessing and integrating multiple sources of information in the process of finding and engaging targets on the task screen, which include both threats and opportunities. Opportunities manifested as enemy vehicles and bases that they could destroy to gain offensive points. Threats manifested on the simulation screen as enemy vehicles and launchers that were capable of destroying team members’ assets, costing the team defensive points. Threats were commonly paired with opportunities to protect them from attack. Each team’s goal was to maximize its performance by identifying and destroying enemy threats and opportunities while avoiding having their own assets destroyed by enemy threats.

Team member roles. Teams were functionally structured with defined, specialized roles and expertise, and each member was responsible for fulfilling the same role throughout the entire simulation. Except for the leader, each other member was randomly assigned to one of four roles in either operations or intelligence positions. The two team members who primarily gathered information about the environment were labeled as intelligence team members, and the two members who engaged threats and opportunities to score points and protect bases were labeled as operations team members.

Members in the intelligence positions were assigned to one of two intelligence roles—signals or human intelligence—and each managed two types of discrete information assets (8 assets of each type for a total of 16 per player and 32 per team) that could be placed anywhere on the game grid in each round to identify threats and opportunities. Each intelligence asset was effective in a different region of the environment and could be deployed to a single location on the screen to gather probabilistic information regarding that area of the environment. These assets could not be lost to enemy threats; however, they were only accurate (at 95 percent) in one area of the simulation environment, known as the “sweet spot.” The sweet spot could be located in the upper half, the lower half, or the middle of the screen, and each of the four types of intelligence assets were only accurate in this specific portion of the task screen. In the rest of the screen, assets would either give no information or, occasionally, false information. Therefore, identifying the sweet spot for each type of asset was a critical responsibility of the entire team.

In contrast, operations team members had four different types of assets: strike, escort, refuel, and information. Strike assets had the capability of capitalizing on opportunities. Escort assets had the capability of destroying threats. Refuel assets enabled other assets to reach distant portions of the environment. Information assets gathered information from areas larger than the areas investigated by intelligence assets. In contrast to intelligence assets, the information that was gathered by informa-
tion assets was always completely accurate (at 100 percent). These assets were controlled by the two operation members—offensive and support. The offensive operation member controlled four strike and four escort assets and was responsible for utilizing these assets in the entire task screen. The support member controlled four refuel and four information assets and was responsible for utilizing these assets to support strike and escort vehicles (refuel assets) or coordinate grid searches with intelligence members (information assets).

Each team’s assigned leader could approve or change the decisions made by the offensive and intelligence team members.

Simulation environment. The environment in the LDS consisted of a grid, 16 rows (1–16) by 16 columns (A–P), totaling 256 squares. At the start of the simulation, teams were presented with a blank grid. However, as shown in Figure 2, hidden throughout the grid were threats and opportunities, which could be either small or large and either fixed or mobile. Threats attacked assets and bases, costing the teams points. Opportunities could be destroyed by strike assets, gaining the team points. Teams needed a single asset to engage a small target, but they needed two assets to engage large targets. Fixed targets remained in the same square throughout the entire simulation, while mobile targets moved around the grid.

Teams engaged in the simulation through a series of rounds, or decision-making periods. During the first three minutes of each round, team members deployed their assets on the simulation grid. Next, the team leader had one and a half minutes to review the team decisions and make any desired changes to the asset allocation. Then, teams viewed the results of their choices, seeing what threats and opportunities their assets had located and engaged,
and had two minutes to analyze this feedback and make decisions for the next round. In total, each team performed the task for ten rounds.

**Procedure**

Three to four weeks before the experimental session (upon signing up to participate in the study), participants completed an online questionnaire that assessed their natural leadership tendencies, described in the section on leadership manipulation below. After team members were randomly assigned to teams, the leader of each team was selected for training on the basis of his or her natural inclination to behave in a directive versus empowering way, depending on experimental condition (as described below). Selected team leaders were trained to exhibit desired leadership behaviors in isolation from the rest of the team, immediately before the start of the experiment.

Upon arriving at the laboratory, participants in staff positions were randomly assigned to operations or intelligence roles, after which they completed a pretask survey (capturing the control variables) and were introduced to the other team members and the purpose of the team task. Next, the entire team was trained with a 30-minute pre-recorded presentation on how to operate the simulation. The team introduction and the training phases mirrored the team formation and task compilation phases of Kozlowski et al.’s (1999) framework. During these early team development phases, members were asked to focus on understanding the group task.”

The individual scoring highest on the directive leadership inclination was chosen for the role of the directive leader in teams randomly assigned to the directive leadership condition. To maximize the difference (and the influence of the manipulation), we used a similarly constructed survey to select the empowering leaders in the empowered teams: participants filled in a survey asking to what extent they felt comfortable performing empowering behaviors while working in a group, such as “taking charge of a group,” “giving instructions to group members,” and “specifying others’ roles in a group task.”

The individual scoring highest on the directive leadership inclination was chosen for the role of the directive leader in teams randomly assigned to the directive leadership condition. To maximize the difference (and the influence of the manipulation), we used a similarly constructed survey to select the empowering leaders in the empowered teams: participants filled in a survey asking to what extent they felt comfortable performing empowering behaviors. The items were adapted from the Empowering Leadership Questionnaire (ELQ), developed by Arnold and his colleagues (2000), and participants responded by indicating (1 = “extremely uncomfortable,” and 7 = “extremely comfortable”) the extent to which they would feel comfortable performing directive leader behaviors while working in a group, such as “taking charge of a group,” “giving instructions to group members,” and “specifying others’ roles in a group task.”
sider ideas and suggestions of group members.” The individual who scored highest on the ELQ in a team randomly assigned to the empowering leadership condition was selected for the role of the empowering leader. Team leaders were not informed of the reason for their selection.

The selected leaders were trained on site, in the simulation lab, immediately before each experiment. Training has been shown to have an impact on leader actions (e.g., Towler, 2003) and to increase the use of desired leader behaviors (e.g., Barling, Weber, & Kelloway, 1996; Towler, 2003), even when a manipulation is only 5 minutes long (e.g., Manz & Sims, 1986). In this study, team leaders received 30 minutes of training, the composition of which depended on their experimental condition. Directive leaders were first exposed to a 10-minute verbal presentation that explained and detailed what kind of behaviors they were expected to exhibit. Then they were shown a short movie clip (from *Apollo 13*) emphasizing the desired directive leader behaviors; the movie clip was followed by a 10-minute role-playing simulation that again emphasized the desired behaviors. For the last 5 minutes of the training, directive leaders were also trained and asked to develop a specific game plan without input from team members and to ask team members to carry out the proposed game plan (Yun et al., 2005).

The selected empowering leaders were exposed to a similar 30-minute training that included a 10-minute verbal presentation, which explained and emphasized the kind of behaviors the leader was expected to exhibit during the simulation; a short movie clip, also from *Apollo 13*, this time emphasizing empowering leader behaviors; and a 10-minute role-playing exercise to strengthen the modeled behaviors. For the last 5 minutes of the training, empowering leaders were asked to develop a plan to include all the team members in setting team performance goals via exchanging ideas and information with one another.

To aid leaders in acting in a directive or empowering manner, we gave them a “cheat sheet” with a list of key verbal prompts that were suggested for use during interaction with the team throughout the simulation. The phrases listed on this cheat sheet (shown in the Appendix), reflect general rules of the simulation rather than specific, expertise-based comments and served simply to reinforce the manipulation. Finally, the leaders were given a statement to read before the beginning of the experiment; the text of the statement emphasized either directive or empowering leader behaviors.

**Team performance.** Team performance was calculated as the sum of a team’s offensive (points gained) and defensive points (points lost) during each round of the simulation and reflected the team’s primary objective, maximizing its score. Teams received points each time they engaged an opportunity or neutralized a threat and lost points each time one of their assets was destroyed by a threat or a threat reached the team base. Specifically, teams scored 4 points for capitalizing on a small opportunity and 16 points for capitalizing on a large opportunity; they scored 2 points for destroying a small threat and 4 points for destroying a large threat; and they lost 8 points for each asset destroyed by a threat and each time a mobile threat reached a base.

**Team learning.** Team learning was assessed by the number of intelligence assets sent to the correct sweet spots (described above) during each round of the simulation. This measure was based on the degree to which a team identified the areas in which its intelligence assets were accurate, which required team members’ joint experimentation and reflective communication about the results of the experimentation (Gibson & Vermeulen, 2003). At the beginning of the simulation, team members were unaware in which part of the grid each type of intelligence asset would accurately identify threats and opportunities. Without accurate information, team members would be unable to engage enemy opportunities and threats, making sweet spot identification critical for team success. To learn the sweet spot areas for each type of asset, team members in all roles had to exchange information received from their own assets, experiment and share their mistakes and successes, integrate the placement of their assets to “double source” a grid square and verify which assets were effective there, and consolidate the information received from their assets with the rest of the team. Once teams learned where intelligence assets were accurate, they were able to send them to the grids on the task screen where they would be most effective—the sweet spots—to identify targets and opportunities for scoring. Therefore, the number of intelligence assets sent to the sweet spots indicated the effective transfer and application of team learning in each round.

**Behavioral coordination.** Our measure of behavioral coordination focuses on the alignment of team member actions toward their interdependent task,
as described by Marks et al. (2001). Specifically, we measured the number of times during each round that strike and escort assets received refueling support from the operations support role to investigate and destroy enemy opportunities and threats identified by intelligence. All missions sent to the north, or top half of the game grid, required refueling support, without which the tasked assets would run out of fuel and be destroyed. For a strike or escort mission to survive a trip to the north, multiple team members must agree on how best to allocate their respective resources and then simultaneously commit them to the same game grid square.

**Team empowerment.** Team empowerment describes a team’s collective sense of having authority and responsibility to control their work and was measured with a six-item measurement instrument adapted from Mathieu and colleagues (2006) (α = .87). Each team member indicated the extent to which they agreed or disagreed (1 = “strongly disagree” and 5 = “strongly agree”) with the following exemplary statements: “In our team members are responsible for deciding how to achieve our goals,” “My team is empowered to change our work processes in order to improve our performance,” and “In our team members have a great deal of freedom in deciding how we will do our work.” We used James, Demaree, and Wolf’s (1984) $r_{wg}$ agreement index to justify aggregating individual members’ response to the team level (mean $r_{wg} = .91$). In addition, we calculated and report here the intraclass correlations (ICCs), which represent whether measures are sufficiently reliable to model effects at the team level. ICC1, indicating the reliability of a single rating of the team construct, equaled .49, and ICC2, which represents the reliability of the average (mean) team members’ responses, equaled .79. Thus, reliability statistics, coupled with our theoretical reasoning, provided support for reliable team-level effects, and we proceeded with aggregating the individual members’ scores to arrive at a single score for each team (Bliese, 2000).

**Team mental models.** To assess team mental model development, we adapted Marks et al.’s (2000) concept-mapping technique, which was specifically designed for tasks such as this (e.g., Ellis, 2006). Following the experimental task, team members were given a task scenario accompanied by eight blank spaces (two per team member) that needed to be filled with one of eight concepts that represented different aspects of team member roles and capabilities. Team members completed the maps by placing concepts that best represented the actions of each team member on the diagram. These mental maps reflect the models held by team members throughout the performance session and were constructed specifically for this study and based on team members’ roles during the experimental task. For example, for the operations support role, team members would need to accurately identify that they possessed refueling and information assets and when they would deploy them.

To arrive at the team-level mental models score, we used each team member’s individual concept map and compared it to each of the other team members’ concept maps, dividing the number of matching responses by the total number of possible dyadic matches to obtain a total team mental model similarity score ranging between 0 and 6.

**Control variables.** In this study, we controlled for two team ability and experience factors that may play a role in team performance and learning: team cognitive ability, in terms of average GPA per team (e.g., LePine, 2003), and team members’ degree of computer game experience, which was measured with a three-item measure ($\alpha = .80$) asking participants to indicate their level of computer game experience (e.g., “How skilled are you in playing computer games?” [1 = “unskilled” and 5 = “very skilled”]). The individual scores were averaged to arrive at a team-level computer game experience score.

**RESULTS**

**Manipulation Checks**

To ensure that leader behaviors were consistent with their experimental condition, we measured the extent to which team members perceived that their leader behaved in an empowering or a directive manner with two five-item instruments adapted from Pearce et al. (2003). We administered the instruments to participants after the end of the simulation to avoid biasing team members’ perceptions of their leader during the simulation execution (Durham et al., 1997). One of the instruments measured *perceived directive leadership*, and the other measured *perceived empowering leadership*. A sample item for empowering leadership read, “The team leader gives the team autonomy and freedom of action,” and a sample item for directive leadership read, “The team leader defines tasks and responsibilities for group members.” Both measures used a scale ranging from 1, “strongly disagree,” to 5, “strongly agree.” The mean $r_{wg}$ for
perceived directive leadership was .77, and each work group $r_{wg}$ value exceeded .70, which is commonly used as a cutoff to justify aggregation of individual-level measures to the group level (Klein & Kozlowski, 2000). Similarly, the mean $r_{wg}$ for perceived empowering leadership was .84. Intra-class aggregation statistics also justified aggregation (Bliese, 2000; James, 1982; Kirkman et al., 2004; Mathieu et al., 2006) to the team level (perceived directive leadership: ICC1 = .22, ICC2 = .63; perceived empowering leadership: ICC1 = .28, ICC2 = .68).

Results indicated that the participants in the directive condition perceived their leader to be significantly more directive (mean = 3.77, s.d. = 0.49) than those in the empowering condition (mean = 3.12, s.d. = .45; $t_{[58]} = 5.35, p < .01$). Similarly, teams in the empowering condition viewed their leaders as more empowering (mean = 3.96; s.d. = 0.37) than teams in the directive condition (mean = 3.05; s.d. = 0.37; $t_{[58]} = 7.81, p < .01$). Taken together, these results provide support for the effectiveness of the two leadership manipulations.

**Measurement Timing**

To test whether the timing of our measures coincided with the theorized phases of team development, we focused on the degree to which teams engaged in risky, experimental behaviors, which are more common in earlier phases—specifically, we counted the number of unescorted missions. In LDS, when an operations asset is sent on a mission, it may be destroyed by enemy threats unless accompanied by escort assets. However, using escorts limits the number of possible missions in each round, making the number of unescorted missions a proxy for risk taking by a team. Results show that the number of unescorted missions in the role compilation phase (rounds 1–5; mean = 2.40, s.d. = 1.60) were significantly higher than in the team compilation phase (rounds 6–10; mean = 1.07, s.d. = 1.32; $t_{[294]} = 8.24, p < .01$), suggesting that teams in the team compilation phase had shifted their focus away from experimentation toward the routines and performance improvement associated with team compilation.

**Data Analyses**

In keeping with the nature of our hypotheses, we used three different statistical analyses. First, we used a two-sample $t$-test to test our first hypothesis (Hypothesis 1), examining the difference in the overall level of team performance in the initial (role compilation) phase of team interaction between the two conditions, directed teams and empowered teams.

To test the nature of the leadership-time interaction and performance improvement hypotheses (Hypotheses 2–4), we estimated random coefficient growth models (RCM), following the six-step model estimation procedure of Bliese and Ployhart (2002). Leadership was entered as a dichotomous level 2 variable (“empowering leadership” = 1 and “directive leadership” = 0), and the team performance scores at each round were entered as a level 1 outcome. We conducted all analyses using the nonlinear and linear mixed effects package (“nlme”) in the statistical software R, version 2.14.0. First, we specified the level 1 model (steps 1 through 4; see Bliese and Ployhart [2002] for a detailed description of the procedure) in which teams’ performance scores were examined for growth over time. Having correctly specified the level 1 model, we examined the level 2 model (steps 5 and 6), in which leadership is entered as a time-invariant team-level variable and the cross-level interaction between time and leadership is used to estimate the extent to which leadership accounts for between-team differences in slope parameters for the time-performance relationship (Hypothesis 2). Repeating the steps outlined above, we again used RCM to examine the mediating effects of team learning (Hypothesis 3) and team behavioral coordination (Hypothesis 4) on performance improvement during the team compilation phase of team development (rounds 6 through 10), following the recommendations of MacKinnon, Fairchild, and Fritz (2007).

Finally, to test our fifth and sixth hypothesis we used generalized least square (GLS) regression analysis to regress the team performance score for each performance round of the team compilation phase on the relevant variable (independent variable and mediators) and control variables. The use of GLS allowed us to use the one-time measures of team empowerment and team mental models (which made it impossible to utilize RCM for Hypotheses 5 and 6) at the same time accounting for the data heteroskedasticity and correlations among the dependent variable multitime longitudinal observations. Having established the relevant regression coefficients, we then constructed bootstrapped confidence intervals to estimate the strength of the indirect path (Preacher, Rucker, & Hayes, 2007).
Hypothesis Testing

The summary of means, standard deviations, and correlations among the study variables of interest is provided in Table 1. None of the control variables were significantly correlated with team performance; however, to increase the robustness of our results, we controlled for them in the subsequent analyses.

Hypothesis 1. Our first hypothesis proposes that teams led by a directive leader exhibit higher initial performance than teams led by an empowering leader. Results of a two-sample t-test comparing the performance results of directive versus empowering teams during the role compilation phase of team development (rounds 1–5) indicated that directed teams (mean = 7.33, s.d. = 14.30) significantly outperformed empowered teams (mean = −3.52, s.d. = 19.01); t(58) = 2.50, p < .05). Therefore, our first hypothesis was supported.

Hypothesis 2. Our second hypothesis proposes that teams led by an empowering leader exhibit greater performance improvement in the team compilation phase than teams led by a directive leader. To test this hypothesis, we built and tested a random coefficient growth model following the six-step procedure outlined in our data analyses section. At steps 1 through 3, we specified our level 1 model and found that (as expected), there was a positive and significant linear trend for the influence of time on team performance (β = 1.62, p < .01). Further, the significant slope variation among teams (as suggested by a log-likelihood comparison of the model with fixed versus random slope effects: −2 log-likelihood = 211.61, p < .01) indicated that the model with the random slopes fitted the data significantly better. Modeling heteroskedasticity as an exponent of the (time) covariate at step 4 additionally improved the fit of our level 1 model (−2 log-likelihood = 57.79, p < .01).

In steps 5 and 6 of the RCM procedure, we specified the level 2 model and, as shown in Table 2, in the final level 2 model, the interaction term involving leadership and time was positive and significant (γ = 0.34, p < .05), providing support for Hypothesis 2. To better understand the cross-level longitudinal influence of leadership (specifically, empowering leadership, coded 1), we plotted the interaction in Figure 3.

As shown in Figure 3, teams led by an empowering leader exhibited lower initial performance and greater performance improvement than teams led by a directive leader, supporting both Hypotheses 1 and 2. We then tested the mediating role of four behavioral, cognitive, and motivational processes and states in explaining the difference in performance between teams with empowering and directive leaders during team compilation.

Hypotheses 3 and 4. Hypotheses 3 and 4 propose that team learning and behavioral coordination, respectively, partially explain the difference in the performance of empowering and directive leadership during the team compilation phase of team development. Given their nature, these hypotheses should be treated as mediated longitudinal moderation (Muller, Judd, & Yzerbyt, 2005). To support these hypotheses, we had to demonstrate that the two mediators—team learning and behavioral coordination—were significantly related to team perfor-

performance improvement while simultaneously leading to a drop in the significance of the interaction term, involving time and leadership. Such a result would indicate that the differential influence of empowering and directive leadership over time became less significant when team learning and team behavioral coordination were included in the equation (see MacKinnon et al.[2007] for a detailed explanation of the procedure).

In testing the first step of the mediated moderation hypothesis, we found that leadership (γ = 9.72, p < .05) as well as the interaction between time and leadership (γ = 1.19, p < .05) were positively and significantly related to team learning during the team compilation phase (Hypothesis 3). Similarly, leadership (γ = 5.69, p < .05) and the interaction between time and leadership (γ = 0.77, p < .05) were significantly related to team behavioral coordination during team compilation (Hypothesis 4). Then, in the next step of our hypothesis testing, we included all of the independent variables (including the two mediator variables) in the RCM equation for team performance. As shown in Table 3, which presents the results of this step, the coefficient for the interaction term involving time and leadership failed to reach significance (γ = 1.24, n.s.), whereas both learning behaviors (γ = 0.39, p < .05) and behavioral coordination (γ = 1.26, p < .01) were positively and significantly related to team performance over time.

To estimate the strength of the indirect effect, we followed the recommendation of Bauer, Preacher, and Gil (2006) and calculated the 95% confidence

interval of the indirect effect by employing the Monte Carlo method for assessing mediation (MCMAM). The calculated confidence interval estimating the strength of the team learning indirect effect (CI = 0.03; 1.07] did not include zero, indicating a significant indirect effect through team learning (Hypothesis 3). The confidence interval around the indirect effect of team behavioral coordination (CI = 0.05; 2.24) also excluded zero, indicating that behavioral coordination accounted for significant variance in team performance improvement (Hypothesis 4). Cumulatively these findings supported both hypotheses.

**Hypotheses 5 and 6.** Hypothesis 5 proposes that team empowerment partially explains the greater performance improvement for empowered teams (compared to directed teams) in the team compilation phase of team development. Hypothesis 6 proposes that team mental models also serve as a simultaneous mediator to explain the greater performance improvement of empowered teams. As noted in the Methods section, we used GLS regression to account for the mediating role of team empowerment (Hypothesis 5) and mental models (Hypothesis 6) in the team compilation phase of development (rounds 6–10). Our results supported both Hypothesis 5 and Hypothesis 6. Specifically, in line with Shrout and Bolger’s (2002) recommendations, the leadership condition was positively and significantly related to each of the mediators (β = .12, p < .05; Table 4, model 1; and β = .53, p < .01, Table 4, model 2), providing support for our reasoning that leadership explains variability in team motivational (team empowerment) and cognitive (team mental models) states. Then, in the final step of the mediation testing, we found that team empowerment (β = 26.14, p < .01, Table 4, model 3) was significantly and positively related to team performance, and the interaction term involving time and leadership failed to reach significance. The 95% bootstrapped confidence interval estimating the strength of the indirect effect excluded zero (CI = 0.95; 5.95). Together, these findings provided support for Hypothesis 5.

Team mental model development was also positively and significantly related to team performance when included in the estimation of the full mediation model (together with team empowerment, leadership condition, and the interaction between time and leadership condition: β = 2.26, p < .05). The interaction of time and leadership failed

to reach significance in the full mediation model, and the confidence interval estimating the strength of the indirect effect excluded zero (CI = 0.17; 2.51), supporting Hypothesis 6.

**DISCUSSION**

Recent theoretical developments and organizational trends have highlighted the benefits of empowering leadership for individuals and teams (Chen et al., 2011; Srivastava et al., 2006; Zhang & Bartol, 2010). However, research examining the effectiveness of empowering leadership on team performance has been far from conclusive, with a number of studies finding evidence that directive leadership may actually lead to higher performance, especially in the cases of action and project teams (Ensley et al., 2006; Yun et al., 2005).

To help resolve this debate and to extend existing theory to clarify some of the theoretical ambiguity regarding their relative benefits, we investigated the influence of empowering and directive leadership on the performance of newly formed teams over time. Our results indicated that although teams with directive leaders started performing well more quickly, their performance plateaued, whereas the emergent cognitions and improved learning and coordination capabilities of empowered teams allowed them to improve over time. These findings offer a number of theoretical and practical implications.

**Theoretical Implications**

Departing from previous research, which has predominantly considered leadership types in isolation (e.g., Mathieu et al., 2006; Srivastava et al., 2006), we directly compare two distinct leadership types to resolve conflicting evidence in the literature about the effectiveness of these leadership approaches for team performance. Doing so provides insight into both when and why empowering and directive leadership approaches are most effective in teams and contributes to debate as to the limits and benefits of empowerment (e.g., Cotton, Vollrath, Lengnick-Hall, & Foggatt, 1990; Leana, Locke, & Schweiger, 1990; Spreitzer, 1995; Wagner, 1994).

Conceptually, our findings confirm the existing notion about the positive influence of empowering leadership found in the literature for individual performance (e.g., Ahearne et al., 2005; Zhang & Bartol, 2010) and for long-standing top management teams (Srivastava et al., 2006) and extend them to action and project teams that undergo team development before reaching their full potential (Kozlowski et al., 1999). However, by demonstrating that empowering leadership comes at an initial performance cost, we highlight an important boundary condition to empowering styles that may help explain some of the inconsistent or weaker effects on performance described in the literature (e.g., Mathieu et al., 2006).

We also extend the empowering leadership literature to consider the critical role of team developmental phases, demonstrating that the influence of leadership manifests directly through emergent team processes and states. Empowering leaders encourage team members to engage in role exchanges and collective investigation in the early role compilation phase of development, in which they learn about their task environment and each others’ areas of expertise to develop team mental models of how to integrate their efforts, gain collective efficacy and commitment through psychological empowerment, and foster routines to coordinate their behaviors (Kozlowski et al., 1999; Pearsall et al., 2010). This time-consuming process puts them at a performance disadvantage compared to teams with directive leaders (who immediately focus on task performance) that rely on their leaders to provide explicit within-team coordination. However, teams with directive leaders are eventually overtaken by empowered teams as they enter the team compilation phase of development and adaptation, in which teams increasingly rely on their routinized processes and shared cognitions to smoothly coordinate their efforts and knowledge and continuously improve their performance (e.g., Edwards et al., 2006; Marks et al., 2000).

By taking a longitudinal approach to examining these two leadership styles, we provide a more nuanced explanation for previous findings. A simple cross-sectional analysis of the final performance in each condition would have revealed no significant difference between styles at that single point in time. Similarly, a midpoint evaluation would have suggested that directive leadership is much more effective than empowering. However, both approaches would have missed the complex relationship between leadership and team member interactions that plays out over time and may explain why previous work has been equivocal. These findings, therefore, help extend both the leadership and team development literatures and provide a framework for understanding when and
at what stages of team development directing team members may positively impact team performance.

Finally, we extend situational leadership theory by identifying four critical motivational, cognitive, and behavioral markers of team development and readiness that help explain why the influence of empowering leadership in the role compilation phase promotes higher continual performance improvement in the team compilation phase of development. The current conceptualization of follower readiness tends to focus on the maturity, commitment, and skill level of individual followers but to neglect the critical team processes and emergent states that allow empowering leadership to be effective at the team level. Teams with diverse expertise, working interdependently on complex tasks, require an investment in time and leader support to develop the behavioral processes, such as learning and coordination, as well as the shared cognitive understanding to effectively perform and adapt. This investment, made through the empowerment of team members during role compilation, takes longer to pay off, but is critical for such teams’ long-term success. However, because directive leaders limit the emergence of these states and processes, these results also raise questions about the central tenet of situational leadership theory, that teams with an initial directive leader will eventually become ready for that leader to switch to an empowering style.

Managerial Implications

These findings also have number of implications for managers placed in charge of teams. First, the time-sensitive nature of the benefits of each leadership style provides a framework for managers to follow depending on the timeline of their task or project. For teams with short-term or emergent engagements and teams facing emergency situations (e.g., surgical, police, military, and flight teams), a directive style may be most appropriate, as teams must be able to immediately perform at a high level and cannot afford the performance delays and learning errors associated with empowered teams (e.g., Bobic & Davis, 2003; Sims et al., 2009; Yun et al., 2005). However, when teams have an extended timeline, as do project or software development teams, or must be able to adapt to complex and changing environments over time, an initial and continuing empowering leadership style may be most appropriate, as it encourages the development of shared cognitive structures, routines for learning and coordination, and feelings of collective competence and commitment during the role compilation phase that set the stage for higher long-term performance.

However, it is important that managers do not misinterpret these findings to conclude that a directive leadership style is beneficial early, but that one should switch to an empowering style as teams progress to the team compilation phase of development. Although there may be some advantage to employing a combination of the two leadership approaches (e.g., Gratton & Erickson, 2007), our results suggest that the benefits of empowering leadership in teams tended to manifest because team members initially engaged in role identification and learning processes during the role compilation phase. Empowered teams, therefore, may not be able to reap the benefits of improved performance over time without first suffering the initial performance delays.

Finally owing to the critical role of team learning in empowered teams, managers who seek to adopt an empowering leadership style should also focus their efforts on facilitating a team learning and information-sharing orientation (e.g., Burke et al., 2006; Bunderson & Sutcliffe, 2003). They can do so by encouraging risk taking and experimentation, and the development of a psychologically safe environment (e.g., Edmondson, 1999; Edmondson, Bohmer, & Pisano, 2001). Recently, Walumbwa and Schaubroeck (2009) found that leaders who engaged in active, ethical leadership created feelings of psychological safety in their followers, leading to higher levels of voice behavior. This suggests that empowering leaders who genuinely value the inputs of their team members and allow them to fail without repercussion may be best able to cultivate an autonomous learning environment. However, it also raises the possibility that leaders who attempt to fake an empowering manner, without having any real willingness to sacrifice their own authority, may be thought of as disingenuous, and the team may never develop the levels of safety so necessary for psychological empowerment and learning.

Limitations and Directions for Future Research

This study also has a number of limitations. First, the scope of this study was restricted to relatively short-term teams put together for a specific complex task (Sundstrom, 1999). In addition, the teams in this study enjoyed very high levels of interdependence, which, coupled with a comparatively
short life cycle, may limit the generalizability of our findings to action and project teams. Although these types of teams are increasingly common in organizations, it is possible that the relationships we examined in this study may evolve differently in long-standing teams or in teams with lower levels of interdependence. For example, in teams with low interdependence, the role specification and task assignments related to directive leadership may lead to even greater performance benefits, whereas the performance improvements associated with empowering leadership may never fully materialize. Similarly, creative teams and teams facing greater task ambiguity may not develop or benefit from the shared cognitions and enhanced coordination associated with empowering leadership. However, those types of teams may still gain higher levels of creative engagement and performance from feelings of engagement and commitment (Zhang & Bartol, 2010).

Second, because this study was conducted in a laboratory, research would benefit from establishing the external validity of our proposed relationships in a field setting. Although controlled settings offer the clear advantage of manipulating variables of interest and reducing causality concerns, certain features of our task might have biased our results. For example, teams in this study operated under a functional structure with distributed expertise that required high levels of information and knowledge exchange for the teams to be successful. A different task, employing a divisional or parallel team structure, for example, might have required less knowledge exchange among team members, activating different team learning processes and behaviors (Ilgen et al., 2005).

Also, these teams were assigned new, inexperienced leaders without any particular technical expertise. Although such situations may be common in many organizations (e.g., recent MBAs are often assigned to lead a product development team without having worked their way up through their new organization), we acknowledge that our leader selection may not mirror the leader assignment process in organizations, in which leaders’ technical skills and/or expertise are the basis of their project assignments. It may be that high levels of skill and experience are particularly beneficial for directive leaders but less important for empowering ones (e.g., Vroom & Jago, 1988), and characteristics of the leaders as well as the teams may moderated the performance trajectories of each leadership style in this study. Further investigation of the important role of leader ability in team development would be valuable for extending our results and bounding the external validity of our findings.

The long-term implications of our longitudinal results are also somewhat ambiguous. Although the performance of empowered teams increased steadily during the team compilation phase, and the performance of teams with directive leaders was flatter, it is impossible to state definitively how long these trajectories would have continued. Although there is no reason to believe that the performance of teams with directive leaders would begin to improve in future rounds of task execution, it is not clear how much longer teams with empowering leaders would have continued to learn and improve, and it may be that empowering teams’ performance would have begun to plateau shortly after our study ended.

Further, although our results suggest that teams with initial directive leaders will not develop the readiness to be empowered, we have little idea of whether initially empowered teams will benefit from future directive leadership. It may be that teams have asymmetric capacities to adapt to new leaders, much as they differentially respond to changes in structure (e.g., Moon et al., 2004) or rewards (e.g., Johnson, Hollenbeck, Humphrey, Ilgen, Jundt, & Meyer, 2006). Further research focused on longer-term teams with multiple types of leaders over time would help to resolve the extent of the influence of leadership on team development and performance.

Finally, although we examined the influence of leadership over the multiple phases of team development described by Kozlowski et al. (1999), we cannot definitively identify the beginning or end of each phase. Teams develop through a “continuous series of phases, with partial overlap at transitions” (Kozlowski et al., 1999: 248), and the timing of our measures was intended to capture the essence of that transition rather than to conclusively, discretely demarcate each phase. Therefore, it would be valuable for future research to examine the longitudinal benefits of empowering leadership over a longer-term task or series of tasks in which the duration of each developmental phase varies.

**Prescribed Leader Behavior Prompter Phrases**

<table>
<thead>
<tr>
<th>Directive Leader Suggested Phrases</th>
<th>Empowering Leader Suggested Phrases</th>
</tr>
</thead>
<tbody>
<tr>
<td>● OK, good performance so far.</td>
<td>● OK, well done so far, team.</td>
</tr>
<tr>
<td>● Now, I need you to listen carefully to my instructions so we can do better in the next rounds.</td>
<td>● I encourage all of you to communicate more in order to improve our team performance.</td>
</tr>
<tr>
<td>● I expect you to stick to your roles and execute them with great diligence.</td>
<td>● OK, let’s discuss our performance and decide what we want to do in order to improve it. Any ideas?</td>
</tr>
<tr>
<td>● Make sure you know what your own assets are and operate them accordingly.</td>
<td>● Let’s try to work together—we need ideas.</td>
</tr>
<tr>
<td>● I want the intelligence players to send all their assets early in the round in the upper/lower half of the grid.</td>
<td>● We need all the information you have on the table—tell your team members what you see and think.</td>
</tr>
<tr>
<td>● Operation players, make sure you refuel when operating in the upper grid.</td>
<td>● How about we try something more creative for the next round? What do you think?</td>
</tr>
<tr>
<td>● Operation players, pay close attention to the mobile targets.</td>
<td>● We need to work together as a team—it is up to us to find a way to get more points.</td>
</tr>
<tr>
<td>● Our tactics for the next round is...you all need to follow this tactic.</td>
<td></td>
</tr>
